ABSTRACT

Background: Organochlorine pesticides used illegally in the storage of cowpeas by some farmers to prevent attack by weevils were known to affect the health of human adversely.

Objectives: This study determined the mean concentration of aldrin, o,p’-DDT, endosulfan, heptachlor epoxide and γ-HCH collected from some markets in South-South of Nigeria, compared these concentrations with set standards and ascertained the incidence of occurrence in cowpeas.

Methods: Forty-eight samples of cowpeas were randomly collected from local markets, identified, authenticated, extracted with dichloromethane using Soxhlet apparatus, cleaned-up with silica gel and analysed in a GC-MS using Restek column.

Results: The mean concentration of aldrin (445.08±6.43) µg/kg, heptachlor epoxide (188.84±3.42) µg/kg, o,p’-DDT (182.24±5.13) µg/kg, endosulfan (142.94±2.05) µg/kg and γ-HCH (243.90±4.01) µg/kg in some markets were high and above the maximum residual limit.

Conclusion: Organochlorine pesticides are used in most of the markets in south-south Nigeria for the preservation of cowpeas and in some cases, two or more were detected in a given sample, which could be due to the addition of a combination of pesticides. The need for regular monitoring by regulatory agencies and for sensitisation of both the farmers and merchants on the danger of using these pesticides in cowpeas preservation is therefore germane.

Keywords:
Liver tissues to release metabolising enzymes [4]. It interacts with endocrine receptors such as androgen and oestrogen [5]. and exposure leads to severe health effect in living things [6]. These have resulted in its ban in many countries, while others allow it to be used for restricted purposes [7].

Commonly used organochlorine pesticides (OCPs) resist chemical and microbiological breakdown [8]. It can be absorbed across the skin, from the lungs and intestinal lining [9]. The biliary and urinary pathways are responsible for its excretion in human [10], while in lactating mother these OCPs are excreted in maternal milk [11] and extreme starvation.

Sharma and co-workers have evaluated the presence of OCPs in foods and the environment by different methods [12]. Sosan and co-worker in 2015 [3] and Olufade and co-worker 2014 [13] have used gas chromatography (GC) in the analysis for OCPs. This study intends to use GC-MS in its analysis with one of the recently introduced columns, Restek Rtx-CL column, with unique selectivity for separation of OCPs and having advantage of a quicker time of run, differentiating times of retention and elution orders in the confirmatory analysis as this column also fulfilled the criteria by U.S. EPA. Optimal performance by the column involves conditioning at maximum temperature to obtain the desired baseline level.

_Vigna unguiculata_ (family: Fabaceae), known as cowpeas is a leguminous plant that has its origin from Africa [14], and popularly cultivated in Middle East, Asia and parts of North America [15]. It is more or less a staple food in the southern part of Nigeria, hence this study was limited to the states in South-South of Nigeria.

There is paucity of information on the concentration of OCPs in cowpeas from the south-south states of Nigeria. Thus the aim of this study was to evaluate the mean concentration of aldrin, o,p'-DDT, endosulfan, heptachlor epoxide and γ-HCH in cowpeas collected from south-south states and to compare these concentrations with set standards and ascertain the incidence of occurrence of these pesticides in cowpeas.

**Materials and Methods**

**Study Area and Sample Collection**

Cowpeas were obtained from local markets (wholesale) in Akwa-Ibom (Oron, Tiam), Bayelsa (Sware, Warehouse, Yenagoa), Cross river (Esuk, Ikom main market, Watt), Delta (Igbudu, Jakpa, Main market), Edo (Aduwawa, Agenebode, Ekehuan, Illushi, Lagos street), Rivers (Oil mill, Rumukoro, Rumukuta). A total of 48 samples (three from each market) were obtained and an estimated 1.2 kg of cowpeas sample were separately collected at random from each location with sterile polythene zip-lock bags, before taken to the Pesticide Research Laboratory of the Faculty of Pharmacy, University of Benin, Benin City, Nigeria and stored immediately at a temperature of 40°C until analysed.

**Reagents and Chemicals**

All reagents used for this study were of high standard and included analytical grade of anhydrous sodium sulphate (Na2SO4) and silica gel was obtained from Oxford laboratory (India). Dichloromethane and acetone were supplied by Labscan (Sigma- Aldrich, USA). In-house purification was used to obtain the distilled water for analysis. Reference standard pesticides for aldrin, o,p'-DDT, endosulfan, heptachlor epoxide and γ-HCH were obtained from Sigma-Aldrich Germany.

**Quality Testing of Cowpea Sample**

The freshly harvested cowpeas sample used for the recovery experiment was obtained from the Faculty of Agriculture Farm, University of Benin, Benin City, Nigeria.

**Sample Preparation, Extraction and Clean-up**

Hand-picked 50 g cowpeas seeds were pulverised using a milling machine (Victoria), after which the powder was properly mixed and 10 g sample was weighed into a white baff which was placed in Whatman pre-extraction thimble of a Soxhlet apparatus, based on the method described by [16], extraction was done by dichloromethane (150 ml) at 60 ⁰C for 3 hrs. Rotary evaporator was used to reduce the extract to 5 ml at 40 ⁰C and subsequently dried with sodium sulphate (5 g). Clean-up was done using 160-200 mesh size activated silica gel (analytical grade) with dichloromethane. The combined eluent was dried in rotary evaporator and reconstituted with 1 ml dichloromethane for analysis (GC-MS). Cowpeas without pesticides were spontaneously analysed.

**GC-MS Conditions**

The GC-MS model QP-2010 (Shimadzu) with splitless/split injector and equipped connected to Restek Stx-CL pesticide column (Length 30m, 0.25mm I.D, 0.25μm thickness) was used to identify...
the target OCPs. An energy of 70 eV was used to
generate the mass spectra by monitoring ions (m/z =
50 - 450) in full-scan and selected recording mode
(SIM). Injection volume and temperature 1 µL and
250 °C respectively. Ion and interface source
temperature were 200 °C and 250 °C respectively,
injection and detection temperatures were adjusted to
250 °C. The column temperature was set at 60 °C
and increased immediately at the rate of 10 °C/min. to
180 °C where it was held for 2 min., this was
increased by 15 °C/min., to 280 °C, and held finally
for 4 min.

**Quantification, Identification and Calculations of
Organochlorine in Cowpea**

External standard method was used to determine the
concentrations of aldrin, ortho, para'-dichloro-
diphenyl-trichloro-ethane (o,p'-DDT), endosulfan,
heptachlor epoxide and gamma-lindane (γ-HCH)in
cowpeas, by extrapolating the peak obtained to those
obtained from standard calibration curve. Linearity
was obtained from the correlation coefficient of the
calibration curve. Retention time was also used in the
identification of the pesticides obtained from the
analysis with that of the standards according to
OJ/EU (2004) [18]. This was further confirmed by
setting the mass spectrometry in the SIM mode.

The limits (LOD) and limit of quantification (LOQ) of
the method were obtained from the signal-to-noise
ratios, with numerical values of 3.0 and 10.0. These
were carried out experimentally by subjecting spiked
samples to sample preparation and clean-up.
Background noise was approximately determined by
analysis of blank samples. Recovery experiment was
estimated by extracting spiked blank and comparing
the values with the quantity of pesticides that were
used to spike the blank cowpea. Precision expressed
as percentage relative standard deviation (% RSD)
was evaluated by analysing samples in triplicate.

**RESULTS**

GC analysis result were evaluated based on the peak
area for each of the analyte, while the quantification
of the unknown concentration was obtained by
interfering the peak areas into the calibration graph
formulae. From Table 1, correlation coefficients (R2)
of this study are above 0.9900, indicating good
linearity for the detector used in the quantification of
the pesticides. The relative standard deviation of the
migratory time was between 3.2 % - 7.5 %, showing
the method to be reproducible. The detection limit
(LOD) 0.14µg/kg, implying that GC could detect
OCPs in the cowpeas matrix at this concentration and
the quantity of pesticides was as low as 0.47µg/kg.

It was observed that the retention time for the
pesticides used for this study ranged from 3.84 to
6.43 min (Table 2). This time is shorter than what was
observed in a previous work executed [13] where the
column used produced a longer retention time of
about 20 min. Restek Stx-CL Pesticides column used
in this study show specificity for organochlorine and
shorter retention time. This unique selectivity and
combination with mass spectroscopy prevented or
reduced interference from the matrix and encouraging
a high throughput.

The highest mean concentrations of aldrin and
heptachlor were observed in Agenebode
(445.08±6.43) µg/kg and Ilubisi (188.84±3.42) µg/kg
markets. The highest mean concentration of
endosulfan (182.24±5.13) µg/kg was detected in Tiam
market, while Oil mill market and Main markets had
the highest mean concentrations of heptachlor
(142.94±2.05) µg/kg and γ-HCH(243.90±4.01)µg/kg
respectively.

Table 3, indicated that the use of endosulfan in south-
south Nigeria is not as popular as aldrin and
heptachlor epoxide, endosulfan was detected in only
eight markets (less than half) compared to a total of
eighteen markets evaluated. Aldrin was detected in
cowpeas collected from seventeen markets while
heptachlor epoxide was observed in cowpeas
obtained from twelve markets (two-third). One-fifth
(20) of the samples analysed are above the MRL,
while about one-half (47) of the samples are below
the MRL and in one-fourth of the samples, were not
detected. Pesticides were generally used in most
south-south markets covered in this study for the
preservation of cowpea. In some markets, two or
three pesticides were found in a cowpea sample, this
could be due to the addition of one of the pesticide
before the transportation of the cowpea and the other
during the storage in the warehouses.

DISCUSSION

The results have shown a wide range of concentrations in different states, indicating a high level of indiscriminate addition of these organochlorine pesticides to cowpea, this could cause serious health problems following its ingestion. Acute poisoning symptoms [19] and deaths have been reported due to high concentrations of pesticides and some of these may have remained largely undocumented, while repeated intake of pesticide laden cowpeas have been reported to cause irreparable damages in different organs [20].

MRL set by EU provides the highest level of these pesticides that is allowed in food items. The half-life of these pesticides allows them to remain on the cowpeas for more than one farming season. This is a course for concern since cowpeas are eaten daily in some household as an alternative and cheap source of protein.

The importance of pesticides to cowpea production cannot be over-emphasised, but a consistent report of high concentration of pesticides from studies done in sub-Saharan Africa [18], has become a matter of public health significance. The consumption of cowpeas or its delicacies laden with high levels of γ-hexachlorocyclohexane (Gammallin) could produce different central nervous system disorders, gastrointestinal effect and death in some cases. Cowpeas area rich source of protein cultivated and consumed daily in sub-Saharan Africa in place of animal proteins that are expensive[21].

Although these pesticides may break down overtime, their metabolic products could be more active than the pesticides. The presence of these metabolites could give a clue as to when the pesticides were applied [22]. Detection of pesticides in cowpeas justifies the need for regular monitoring of cowpeas by regulatory agencies and the need for sensitisation of both the farmers and merchants on the danger of using these pesticides in food preservation.
CONCLUSION

Organochlorine pesticides are used in most of the markets in South-South Nigeria for the preservation of cowpeas and in some cases, two or more were detected in a given sample, which could be due to the addition of a combination of pesticides. The need for regular monitoring by regulatory agencies and for sensitisation of both the farmers and merchants on the danger of using these pesticides in cowpeas preservation is therefore germane.
